In CMOS devices, interconnects typically connect together a source region to a drain region and a gate to a gate dielectric layer. The interconnects are typically made up of a titanium silicide (TiSi₂) layer. However, TiSi₂ has a higher sheet resistance, compared to other metals, and the sheet resistance of TiSi₂ for example, at the typical distances between interconnects can be large enough to cause poor circuit performance. One way to improve the performance of interconnects is to reduce the sheet resistance of the titanium. This can be accomplished by forming the titanium at a lower temperature. However, at lower temperatures, the titanium is less likely to form a silicide. Moreover, the thickness of the titanium must also be reduced in order to keep the sheet resistance of the interconnects at a minimum. This reduction in titanium thickness makes the formation of a silicide at such lower temperatures difficult, because the presence of a thick layer of titanium at the surface of the silicon interferes with the formation of a silicide. Accordingly, there exists a need in the art for a method of forming interconnects, having minimal sheet resistance. There exists a further need for a method of forming interconnects which can be performed at a low temperature, thereby minimizing the
